\$sp	29	stack pointer
\$fp	30	frame pointer
\$ra	31	return address

Definitions

- Jump to target address: JTA = concat((PC + 4)_{31:28}, address(label), 00₂)
- Branch target address:BTA = PC + 4 + signext(imm) * 4

Clarifications

- All numbers are given in decimal form (base 10).
- Function signext(x) returns a 32-bit sign extended value of x in two's complement form.
- Function zeroext(x) returns a 32-bit value, where zero are added to the most significant side of x.
- Function concat(x, y, ..., z) concatenates the bits of expressions x, y, ..., z.
- Subscripts, for instance X_{8:2}, means that bits with index 8 to 2 are spliced out of the integer X.
- Function address(x) means the address of label x.
- NOP and na mean "no operation" and "not applicable", respectively.
- shamt is an abbreviation for "shift amount", i.e. how many bits that should be shifted.
- addu and addiu are misnamed unsigned because an add operation handles both signed and unsigned numbers in the same way. The term unsigned is actually used to describe that the instruction does not throw overflow exceptions.
